Execution Context

What are phase in execution phase

Global Execution Context

JS OOPS

globalThis

The globalThis is use to refer the global object of a given environment

new keyword

this

this in Strict vs this in non strict mode

Inplicit binding

Explict Binding

Important Methods

Call

Apply

Bind

Bind Polyfill

```
Function.prototype.$bind = function (ctx , ...args) {
    const fn = this
    return function (...secondArgs){

            return fn.apply(ctx , [...args ,...secondArgs ])

    }
}
```

Partial Application

The partial application is used to prefill the arguments , or to say the **partial application returns a function that requires less args**.

Use Cases of Bind Like Partial Application

```
function add(a , b){
    console.log(a+b)
}

const addWith2 = add.bind(this , 2); // this will return a function with first argument as 2

console.log(addWith2(1)) // 3
console.log(addWith2(2)) // 3
const nestedAddWith2 = addWith2.bind(this , 2);
console.log(nestedAddWith2())// 4
console.log(nestedAddWith2(1)) // 4
```

Most useful example of Partial Application of Bind

What You just saw in the below example is that bind returns a function in which you need to pass less arguments or to **say it just Prefills The arguments**

```
import {useState , useEffect} from "react"

export default function App(){
    const [state , setState] = useState(() =>({}))
    function setStateOnChange(inputName , evt){
        return setState(($state) => (
            {
                ...$state,
                [inputName]: evt.target.value
            }
        ))
    }
    return (
        <div>
            <form>
                <input onChange={setStateOnChange.bind(this , "firstName")} />
                <input onChange={setStateOnChange.bind(this , "lastName")} />
            </form>

        </div>
    )
}
```

Objects

structuredClone

getters

Like in vue js we had **computation** property in this we have getters in case while getting avalue or a peroperty of an object we need to computate something we use the **getters** for it ;

```
    <!-- totalMoney: 10000000, -->
const abhishek = {

    get balance(){
        return "Mind Your Own Business"
    }

}

const rect = {
    length : 100 ,
    breadth : 100 ,
    get area(){
        return this.length * this.breadth
    }
}
console.log(rect.area) // 10000 (will run the function but you can use it as a property)
```

setters

The setters property are **not enumerable** so you wont get the via Objec keys .
The Getter And Setter can be removed via delete keyword

```
const user = {
    firstName: '',
    lastName:'',
    set fullName(name){
        [this.firstName , this.lastName] = name.split(' ')
    }
}
user.fullName = 'Saksham Bakshi';
//user.firstName = Saksham
//user.lastName = Bakshi it will be set via that funcation
```

(getters and setters) vs Proxy

enumerable

The enumerables in js means those properties on js Object that can be viewed and that be looped like via **for of** loop or what you are returned via **Object.keys**

Protype Changing

Shadow properties

The ways tp set Portotype

There are 2 kinds of way to do this:

- Object.create
- Object.assign

Object Create

The Object.create can be used to create a protype propert on an Object

```
const parentObj = {
    methods(){
        console.log(this.name)
    }
}

const childObj = Object.create(parentObj)
childObj.name = "This Will Console when you invoke methods on ChildObj"
```

```
function Shape(){
    this.x = 0
    this.y   = 0

    function move(x , y ){
        [this.x , this.y]=[x , y]
    }
}
function Rect() {
    Shape.call(this)
}
Rect.prototype = Object.create(Shape.prototype ,{
    contructor:{
        value: Rect,
        writable: true
    }
})
```

Important Methods

hasOwn()

It returns the **boolean value** whether the given object and **propertyName** string (key) and telling whether its inherited or its own property

assign

-It only works on the enumerable property or those property that can be assigned or Reset. Basically all the property that are not inherited and existed to an object .

getPrototypeOf()

The getPrototypeOf is a method in which will the parent or immediate prototype of the given object. You can find all the parent

```
obj = Date
do {
    console.log("Start" ,obj)
    obj = Object.getPrototypeOf(obj);

    console.log("Finish" ,obj)
}while(obj)

//Object protype is null so it will end
```

setPrototypeOf()

```
> const parentObj = {
    methods(){
        console.log(this.name)
    }
}
const childObj = {
    name:"Child"
}

const InheritObj = Object.create(childObj , parentObj)
< undefined
> InheritObj
< ▶ {methods: undefined}
> inc = Object.setPrototypeOf(childObj , parentObj)
< ▶ {name: 'Child'}
> inc.__proto__
< ▼ {methods: f} ℹ
      ▶ methods: f methods()
      ▶ [[Prototype]]: Object
> inc.methods = null
< null
> parentObj
< ▶ {methods: f}
> inc.__proto__.methods
< f methods(){
        console.log(this.name)
    }
> inc.__proto__.methods = null
< null
> inc.__proto__.methods
< null
```

The setPrototypeOf takes **childObject parentObj** or prototype take it as parameter and then mutatate the childObj directly by setting up its prototype to a parentObj **and mutatate directly** and the prototype is marked as refrence so if the protype method or property is set the original parent obj also change

```
const parentObj = {
    methods(){
        console.log(this.name)
    }
}
const childObj = {
    name:"Child"
}

const InheritObj = Object.create(childObj , parentObj)
undefined
InheritObj
{methods: undefined}
inc = Object.setPrototypeOf(childObj , parentObj)
{name: 'Child'}
inc.__proto__
{methods: f}methods: f methods()[[Prototype]]: Object
inc.methods = null
null
parentObj
{methods: f}methods: f methods()length: 0name: "methods"arguments: (...)caller: (...)[[FunctionLocation]]: VM90:2[[Prototype]]: f ()
[[Scopes]]: Scopes[2][[Prototype]]: Object
inc.__proto__.methods
f methods(){
        console.log(this.name)
    }
inc.__proto__.methods = null
null
inc.__proto__.methods
```

assign vs Create

The assign is to assign the property to new object and were as in the create a protype on object

is

It is used to compare two value wether two value is same mind it cqan help you to detect wether the object is of same refernce not having same value
![Link]("Link" https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/Object/is)

isExtensible

isFrozen

isPrototypeof

Its **not a static method but a prototype** it helps us to check the protype of the object like for Example

```
function Foo(){}
function Boo(){}

Boo.prototype = Object.create(Foo.prototype)

const bar = new Boo();

console.log(Foo.prototype.isPrototypeOf(bar))
console.log(Boo.prototype.isPrototypeOf(bar))
```

isSealed

isSealed vs isFrozen

keys

The Object.keys() helps us to get array of keys String of an object passed in arguments

entries

The entries static method returns the enumerable properties **keys and value subArray**

```
Object.entries({key:'value'})
[
    [key , value ]
]
```

value

The Object.value() returns the values array of the object

keys vs entries

The **keys vs entries** method takes same type and value of argument and key return just array of key (string) and in the case of entries you can get sub-array of key and value

preventExtension

The preventExtension method takes object as an argument and makes unextensionable i.e you will not be able to add new property

freeze

The freeze niether let you add new property or update , delete protery or change the property descruptor and it works different with strict mode

```
Object.freeze(obj)
Object.defineProperty(obj, "ohai", { value: 17 });
Object.defineProperty(obj, "foo", { value: "eit" });

// It's also impossible to change the prototype
// both statements below will throw a TypeError.
Object.setPrototypeOf(obj, { x: 20 });
obj.__proto__ = { x: 20 };
```

seal

It just lets you modify existing value

seal vs freeze vs preventExtension

Actions	Object.prevent Extensions	Object.seal	Object.freeze
Can add a new property.	✗	✗	✗
Can modify values of existing properties.	✓	✓	✗
Can delete existing properties.	✓	✗	✗
Can reconfigure existing properties.	✓	✗	✗

defineProperty

Helps to define propert with descriptors
enumerable; configurable; writable; value

What are property Descriptors??

The propert descriptors are the property typeof object like is it a **getter , setter ; enumerable ; configurable ; writable ; value**

JS DS ALGO ISSUES

- sliding window
- two pointer technique
- SORTING
- LINCKED list

Function

Currying

Closures

Using closures for private property

Aync Activities

Promises

States

- Fuffiled
- Setlled
- Pending
- Rejected
  Even if a promises is fuffiled and then also you called the **then method** it will stil be executed and they will be called after the **call stack** is cleared and then they will be executed

Settled

The Settled state refers to the state when the Promise is either fullfilled or rejected , that means **the promise is said to be settled if either its accepted or rejected**

Promise constuctor Methods

then()

It takes 2 args the first one is the cb when the the promise is successfuly resolve and the other one is to used one their are some issue and for the **reject or catch phase**,
A promise paryicaipate more than one nesting or for multiple then .4
Even if the Promise is resolved and it has executed its success method even after that if you invoked the then() method it will still execite its callback in the next call stack cycle

```
const somePromise = new Promise(someFunc)
somePromise.then(onResolve , onReject)
somePromise.then(onResolve , onReject)
// both could be inviokled
```

catch()

Its for the error handling

finally

Promises Static Methods

	Either…	
	resolved	rejected
`Promise.all()`	all	any
`Promise.race()`	any	any
`Promise.allSettled()`	all	
`Promise.any()`	any	all

Interview Question of Bacancy

What if something happens in allStelled or any or anyother method when the single one is rejected and you wnat to start again ????

allSettled

If **all resolved and all rejected**

any

If **any resolved and any rejected**

---

all

If **all done any rejected**

race

If **any done all rejected**

reject

resolve

async/await

Promises vs async/await

clearInterval

Advance Topics

Memorization

Debouncing and throttling

For read thsi

Debouncing

What debouncing does is that whenver a function is called which is debounced it will run it after given/specified interval of time if during that the wait duration another invoaking is done it will reset the time and start againb the time unless the last even is fired and after that given duration it will execute

```
function basicDebounceImplementation(fn , duration){
    let debounceTimer = null ;
    return function (){
        const [context , args] = [this , arguments]
        if(debounceTimer) clearInterval(debounceTimer); // the more you call the  later  the function will be called
        debounceTimer = setTimeout(() => fn.apply(context ,args) , duration))
    }
}
```

Rate Limiting

Throttling

What throttle does is that it execute the function and waits for the given time and even through the same function is being called or same event is running it will pause for a given duration after that if the event continous it will run it and then pause the repeated execution for that time

Rate Limiting

```
function basicThrottlingImplementation(fn , duration ){
    const isThrottling = false
    return function (){
        if(isThrottling) return null
        const [context , args] = [this , arguments];
        isThrottling = true;
        setTimeout(() =>{isThrottling = false} , duration)
        fn.apply(context ,args )
    }

}
```

Script Loading

Defer

Async

AbortController

[Docs (https://developer.mozilla.org/en-US/docs/Web/API/AbortController/signal)](https://developer.mozilla.org/en-US/docs/Web/API/AbortController/signal)

The AbortController is a really helpful if you want to cancel WEB API network call and anything async (like **event handler** and **websocket**) and its really helpful to manage un-nessary calling going out and manage wrong cb running and unnesscary load on the server .

AbortController Comes it with its event as well

We can event listen on signal that whether the particaly **Controller** is aborted or not so for example when some contoller is aborted you wnat to some request to a server or log or perform anyther action this is the place and we can also use this to abort anything that does take signal example websocket

---

Network Call AbortController

I have used this in reall time sports betting application as user can select any sport page and if the user changes very fast befor previous one is even loaded this can create a unnessary work to be done both backend and frontend and it will show the previous sport and the next support according how their network are being completed and how ther callbacks are being executed but if user have changed or selected a new sport and aprevious one is not loaded just cancelled it .

Understand this with the **Netflix** example if you select stranger game and you say fuck off lets watch something old school like **friends** and meantime it the stranger game is still being fetched and a spinner on the page and the user clicks on the back button and click your new old school show it will now be loading both the starger game and friends . But with the help of our hero abortcontroller you can cancel stranger games and only load the friend saving both server resouces and the client resources.

```
// a video play example
let controller

let playbutton = doument.getElementById("play")

let abortButton = document.getElementById("abort")

abortButton.addEventListner('click' , () =>{
    if(controller){

        controller.abort();

    }

})

function fetchVideo(){

    controller = new AbortController();
    const signal = contoller.signal

    fetch("ENTER_YOUR_URL" , {signal}),then(resp =>{
        controller = null

    }).catch((err)=> {
        console.error(err);
    })

}
```

Event Handler Abort Controller

Turns you can use abortcontroller to stop / abort event as well. It can be used to remove events , example you have many hundres all event register and you want to remove it togther you can passing the signal property and cancel/remove all the event handler

```
const controller = new AbortController();
const signal = controller.signal ;

const button1 = document.getElementById('btn1')
const button2 = document.getElementById('btn2')
const button3 = document.getElementById('btn3')

button1.addEventListner('click' , function (){
    console.log("Just console on click")
} , {signal})
button2.addEventListner('click' , function (){
    console.log("Just console on click")
} , {signal})
button3.addEventListner('click' , function (){
    console.log("Just console on click")
} , {signal})

const removeBtn = document.getElementById('removeBtn')
removeBtn.addEventListner('click' , ()=>{
    controller.abort() // aall event wil be removed
})
```

Custome Use Case

Lets just consider you want to abort a websocket which doest not take signal as a parameter.

```
const controller = new AbortController();
const {signal} = controller

function initWebSocket(){
    const soket = new Websocket();

    if(signal.aborted){
        socket.close();// incase if controller befir the connection is made
    }

    signal.addEventListner('abort' , () => socket.close( ) , {once: tue } /*once is passed to tell it should only be run one time
only*/) // you can use to aort event to make your custom abort for async process like file action , stream , etc
}
```

It can be use for exiting heavy process

generator in js

- The yield is used to pause the function and is used to give out the value
- the yield also take the value and start it again from where it had left (We can pass in the value to another yield expression .)
- *yield its used to pause and delegate it to anyother gernator function outside its generator function .

After the invocation of that function you get the **iterable object** with a **done** property and a **value** .
The value will be false and to resume **next method** we can continue to this until **done** is **false**

MutationObserver

Service Worker

IndexDB

EVENTS Concept of JS

Bubbling vs Capturing

Capturing

Its by default false

Bubbling

stopPropogation()

Event Delgation

Use in the case of the bubbling as image you ve the hundred of li or lots of sibling element instead puting evengt on each one of them you can add and ommponent parent and listen the event over there via the property of the Bubbling

currentTarget vs target

- The currentTarget provided you with the element on which the event listner is added but in the case of the target it tells you where the event is triggered or actaul event happends.

Load vs DOMContentLoaded

DOMContentLoaded is loaded when the dom is parsed and load when all the script , styles are loaded
